

STAR LIFE CYCLE

From Nebula to Stellar Endings

A star's mass helps determine its life cycle.

STAR LIFE CYCLE

From Nebula to Stellar Endings

NEBULA

A giant cloud of gas and dust where stars are born.

1. AVERAGE STAR

A star like our Sun shines steadily for billions of years.

2. RED GIANT

The star expands and cools as it burns its fuel.

3. WHITE DWARF

The core shrinks and cools, leaving a small, dense white dwarf.

1. MASSIVE STAR

A very massive star burns fuel much faster and is much brighter.

2. RED SUPERGIANT

The star expands dramatically and becomes a red supergiant.

3. SUPERNOVA

The core collapses and the star explodes in a powerful supernova.

4a. NEUTRON STAR

The core collapses into an incredibly dense neutron star.

4b. BLACK HOLE

If the core is very massive, it collapses into a black hole.

A star's mass helps determine its life cycle.
